A critical study of academic anxiety among male adolescents

Dr. Shrikant S Mankar

Abstract

The present study was conducted to examine academic anxiety among male successful, unsuccessful and non-athlete adolescents. Total three hundred (N=300) male adolescents which include one hundred (n=100) successful athletes, one hundred (n=100) unsuccessful athletes and one hundred (n=100) non-athlete adolescents were selected to act as subjects. The successful athletes were those who won medals in the inter-school tournaments whereas unsuccessful athletes were those who had just participated but failed to won medals in the inter-school tournaments and non-athletes were those who did not participate in any inter-school tournaments. Random sampling technique was applied to select the subjects studying at various Government schools of Nagpur. Academic anxiety was measured by applying the Academic Anxiety Scale for Children constructed by Singh, A.K. and Gupta, A. Sen (2009). The One way Analysis of Variance (ANOVA) was applied to find out the significance of differences among male successful, unsuccessful and non-athlete adolescents. The level of significance was set at 0.05. Results showed statistically significant (p<0.05) differences among male successful, unsuccessful and non-athlete adolescents with regard to the variable academic anxiety. Since the obtained F-value 7.285 was found statistically significant, therefore, Post-hoc test i.e., Least Significant Difference (LSD) was applied to see the degree and direction of differences among male successful, unsuccessful and non-athlete adolescents. The non-athlete male adolescents had exhibited significantly higher academic anxiety followed by unsuccessful and successful athlete adolescents.

Keywords: Academic anxiety, successful, unsuccessful, non-athlete, male, adolescents

Introduction

Anxiety is a common phenomenon of everyday life. It plays a crucial role in human life because all of us are victim of anxiety in different ways (Goodstein and Lanyon, 1975). Generally, anxiety can be either a trait anxiety or a state anxiety. A trait anxiety is stable characteristic or trait of the person. A state anxiety is one which is aroused by some temporary condition of the environment such as examination, accident, punishment, etc. Academic anxiety is a kind of state anxiety. Thus, the academic anxiety has emerged as one of the most salient constructs in modern-day psychology and by far the most widely studied specific form of anxiety in the literature. Academic anxiety is a psychological condition in which a person experiences distress before, during or after a test or other assessment to such an extent that this anxiety causes poor performance or interferes with normal learning. It deserves its notice due to its prevalence amongst the students’ populations of the world (Mandler and Sarason, 1952). Suinn (1968) described academic anxiety as an inability to think or remember a feeling of tension, and difficulty in reading and comprehending simple sentences or directions on an examination. Spielberger and Vagg (1995) viewed academic anxiety as a ‘situation specific form of trait anxiety’, which is explained as a stable personality characteristic and ‘state anxiety’ is a transitory emotional state. Academic anxiety is believed to be the trait that predisposes individuals to react negatively to examinations and test (Keogh and French, 2001). Academic anxiety is a normal response to the pressures of school. It can motivate students to study for tests or complete assignments. Sometimes, however, the anxiety can reach levels that hinder academic performance instead of improving it. Some students delay, others cannot concentrate on studies. Academic anxiety can adversely affect the performance on tests as well. Sarason (1959) had examined the research literature on test anxiety among school children and concluded that the performance of high test anxious students may be both facilitated and impaired by experimental conditions. Personal evaluation or threat leads to decrements of the performance of high test anxious students whereas reassurance facilitates their performance. Achievement oriented instructions impair the performance of high test.
Methodology

Sample
For the present study, total three hundred (N=300) male adolescents which include hundred (n=100) successful athletes, hundred (n=100) unsuccessful athletes and hundred (n=100) non-athlete adolescents were selected to act as subjects. The successful athletes were those who win medals in the inter-school tournaments whereas unsuccessful athletes were those who had just participated but failed to win medals in the inter-school tournaments and non-athletes were those who did not participate in any inter-school tournaments. Random sampling technique was applied to select the subjects studying at various Government schools of Nagpur.

Tool
For measuring Academic Anxiety among male successful, unsuccessful and non-athlete adolescents, the Academic Anxiety Scale for Children constructed by Singh, A.K. and Gupta, A. Sen was administrated.

Statistical design
The one way Analysis of Variance (ANOVA) was applied to find out the significant differences among male successful athletes, unsuccessful athletes and non-athlete adolescents. Post-hoc test i.e., Least Significant Difference (LSD) was applied to find out the direction and degree of differences where ‘F’ value was found significant. To test the hypothesis, the level of significance was set at 0.05.

Results and Discussion
The results with regard to variable academic anxiety among male successful, unsuccessful and non-athlete adolescents have been presented below:

Table 1: Analysis of variance (ANOVA) results with regard to the variable academic anxiety among male successful, unsuccessful and non-athlete adolescents

It is evident from Table 1 that results of Analysis of Variance (ANOVA) with regard to variable academic anxiety among male successful, unsuccessful and non-athlete adolescents were found statistically significant (p<0.05). Since the obtained F-value 7.285 was found statistically significant, therefore, Post-hoc test i.e., Least Significant Difference (LSD) was applied to find out the degree and direction of differences between paired means among male successful, unsuccessful and non-athlete adolescents. The results of Post-hoc test have been presented in Table 2.

Table 2 showed insignificant difference between successful athletes and unsuccessful athletes. However, significant difference was noticed between successful athletes and non-athlete adolescents. It is further observed that the non-athlete adolescents had exhibited significantly higher academic anxiety than their counterpart successful athletes. Similarly, significant difference was also noticed between unsuccessful athletes and non-athlete adolescents. The non-athlete adolescents had demonstrated significantly higher academic anxiety than their counterpart unsuccessful athletes. The graphical representation of mean scores is exhibited in Figure 1.

Discussion
It is noticed from the results presented in Tables (1-2) that there is significant difference found among male successful, unsuccessful and non-athlete adolescents with regard to the variable Academic Anxiety as the obtained F-value 7.285 was found statistically significant. However, while comparing the mean scores of all the groups, it was observed that male successful athletes had exhibited controlled academic anxiety than their counterpart unsuccessful and non-athlete male adolescents. The outcome of the result might be due to the fact that male successful athletes were less occupied by mental tension and also able to manage/control their negative thoughts and emotions. Because it is believed sports participation provides ample opportunities for emotional outlet to its participants and enables them to regulate negative emotions associated with the environment as well as make them to do better on the task at hand.

Sheikhi et al. (2012) revealed statistically significant differences with regard to anxiety between girl athlete...
students and non-athletes. The mean scores showed that girl athletes exhibited lower anxiety as compared to non-athletes. Similarly, De Moor et al. (2006) corroborated that male and who were involved in various physical activities had average anxiety as compared their non-participant counterparts. They substantiated that regular exercise is cross-sectionally associated with lower neuroticism, anxiety and depression and higher extraversion and sensation. Schurr et al. (1977) had clearly reported that athletes were independent, more objective and less anxious than non-athletes. Thomas et al. (1994) expressed that there is a positive association between physical activities and cognitive abilities. They concluded that participation in physical activities leads to positive psychological outcomes as it improves learning ability, memory, lowering anxiety and enable an individual to perform his/her work efficiently with confidence and less self-doubt.

Conclusion
It is concluded from the findings that significant differences were observed among male successful, unsuccessful and non-athlete adolescents with regard to the variable academic anxiety. It is further summarized that male non-athlete adolescents had exhibited significantly higher academic anxiety than male unsuccessful athletes. Similarly, the male unsuccessful athletes demonstrated higher academic anxiety than male successful athletes. Finally, the male successful athlete adolescents showed controlled academic anxiety.
